Condition Monitoring Solutions for Reciprocating Compressors
Why Monitor?

As one of the oldest compressor designs, recips enjoy unique capabilities and are quite flexible with features such as broad capacity control ranges and the ability to compress gas regardless of mole weight or k value. Add multiple stages and they can compress a gas to extremely high compression ratios. Consequently, they are an ideal fit for selected applications—such as hydrogen compression in the de-sulfurization process of many refineries—and as part of the low-density polyethylene production process in chemical plants, to name just a few.

However, reciprocating compressors suffer from one very serious drawback: high maintenance costs. In fact, compared to similarly sized centrifugals, recips can consume as much as five times the amount of maintenance dollars.

That’s why a continuous monitoring system is so important. Specifically designed to meet the unique machinery protection and condition monitoring needs of recips, our solutions, which include Safety Integrity Level (SIL) certified products can help close the gap, bringing your recip maintenance costs closer to the levels associated with centrifugals while simultaneously improving reliability, availability, and safety. And, with patented† technology, comprehensive services, and over 25 years of experience monitoring reciprocating compressors, no one is better equipped to help you.

† United States Patents 4,987,774; 6,421,571; 6,826,490; 6,937,941; 6,934,696 and 8,297,123. Great Britain Patent 2,408,338.
Recips can consume five times as many maintenance dollars as an equivalently sized centrifugal compressor.

A monitoring system from GE will often more than pay for itself in the first year, and can save millions of dollars over the life of the compressor.
Recip Monitoring In Detail.

**Pressure Packing Case Temperature**
Continuous monitoring of pressure packing temperature provides useful information on developing problems related to the packing, including excessive wear, insufficient cooling, and inadequate lubrication.

**Packing Vent Line Temperature**
Continuous monitoring of packing vent line provides an indication of leaking purge packing. With an increase in process flow, the vent line becomes hotter. For years, operators have used the subjective method of touching the line to see if gas is leaking.

**Continuous Rod Load**
Combined inertia and gas rod loads are calculated at the crosshead pin. This provides information on rod bow and rider band wear. Continuous monitoring gives maximum magnitude and direction of rod movement along with the crank angle at which the maximum occurs. The source of movement can be identified, enabling the proactive scheduling of maintenance for rider band replacement or crosshead repair. Monitoring plunger position in hyper compressors provides protection against deteriorating plungers.

**Cylinder Pressure Profile**
The single most effective way of determining the overall health of a reciprocating gas compressor is by examining the cylinder pressure profile. Online access to the internal pressure for each compressor chamber enables continuous monitoring of cylinder pressures, compression ratios, peak rod loads, and rod reversal. This provides valuable information on the condition of suction valves, discharge valves, piston rings, packing glands, and crosshead pin. And, interfacing the 3500 System with System 1 software provides valuable diagnostic plots such as Pressure versus Volume (P-V), Log P versus Log V, and Pressure versus Crank Angle (θ-P-T).

**Cylinder Acceleration**
Placing accelerometers on the cylinder provides waveform information that can be combined with cylinder pressure data to assess the health of the cylinder valves. This information has significant value when hydraulically actuated valves (stepless unloaders) have been installed on a compressor. For compressors so equipped, cylinder acceleration is strongly recommended.

**Multi-Event Keyphasor Signal**
A proximity probe observing a multi-toothed wheel on the crankshaft provides a precise reference timing signal every 30 degrees of rotation in addition to a once-per-turn reference point. This allows measurements such as rod position and cylinder pressure to be correlated with a highly accurate crank angle measurement. Rod position can be captured at the same point in the piston rod stroke, and cylinder volume can be computed precisely at each point in the stroke for highly accurate P-V curves.

**Crosshead Shoe Temperature**
Main Bearing Temperature
This measurement indicates problems related to fluid-film bearings, including overload, bearing fatigue, or insufficient lubrication.

3500 Monitor: 3500/65 16-Channel Temperature Monitor

Crosshead Vibration

Crosshead-mounted accelerometers can detect machinery problems due to impact-type events such as excessive crosshead clearance, liquid ingestion into the cylinder, excessive clearance in the crosshead pin bushing and lose or cracked nuts, bolts, liners or pistons.

Crosshead Shoe Temperature

Continuous monitoring of crosshead shoe (slipper) temperature provides useful information on developing slipper problems such as overload, fatigue, and insufficient lubrication.

Suction/Discharge Valve Temperature

Suction and discharge valves are typically the highest maintenance items on recip. Faulty valves can significantly reduce the compressor’s efficiency as well as increase combined rod load. By recompressing the same gas, a leaky valve becomes hotter than normal, causing the valve cover plate temperature to increase. By monitoring both absolute valve temperature, and differential temperature between a group of valves, valve problems can be spotted early and repaired before efficiency losses mount.

3500 Monitor: 3500/61 6-Channel Crosshead Shoe Monitor

or 3500/65 16-Channel Temperature Monitor Transducer: RTD or Thermocouple

Suction Gas Temperature

Continuous monitoring of suction gas temperature provides a useful baseline against which to compare suction valve temperature. Relative changes in the temperature between suction valves and suction gas can give an indication of the worn suction valves. In addition, suction gas temperature, combined with the integrated equation of state engine in System 1 software, provides the information necessary to calculate capacity at suction conditions and cylinder flow balances numbers.

3500 Monitor: 3500/61 6-Channel or 3500/65 16-Channel Temperature Monitor Transducer: RTD or Thermocouple

Suction and discharge valves are typically the highest maintenance items on recip. Faulty valves can significantly reduce the compressor’s efficiency as well as increase combined rod load. At the heart of our Recip Monitoring Solution is the Bently Nevada* 3500 Series Machinery Protection System...

Integrated Machinery Protection and Machinery Management

Our powerful 3500/22M TDI Rack Interface Module eliminates the need for bulky external data acquisition hardware or special interface modules between the monitor rack and software. Simply plug an Ethernet cable into the 3500/22M and you’re ready to communicate with our powerful System 1 software for advanced diagnostics, condition monitoring, and other plant asset management functionality. The result is a zero-footprint solution requiring absolutely no additional rack or cabinet space when augmenting your basic machinery protection system with System 1 connectivity.

And, the enhanced data collection technology of our 3500/22M TDI allows earlier and improved diagnosis of previously difficult-to-ascertain transient events (such as cylinder liquid ingestion).

- Available in 19” 14-slot EIA rack or space-saving 12” 7-slot mini-rack.
- Available with a variety of high-quality display options ranging from self-configuring VGA touch screens to remote workstations to LCD panels that mount directly on the rack face.
- Monitor modules available with 4-20 mA recorder output signals for interfacing with strip chart recorders and other analog based control and automation equipment.
- Safety Integrity Level (SIL) certified monitor modules are available for use in Functional Safety applications.

All monitor modules are totally software configurable via the 3500’s Rack Interface Module—key lockable to prevent unauthorized tampering.

Keyphasor module accepts multi-event-per-turn signals for greater accuracy—required for reciprocating compressor applications where crank angle must be precisely determined.

Highly reliable power supplies accept worldwide AC/DC voltages/frequencies and can be ordered as fully redundant to assure uninterrupted performance.

6- or 16-channel temperature monitors accept a variety of RTDs or thermocouples. Absolute and differential alarming capabilities allow the monitors to be used for valve temperatures, gas or other process temperatures, bearing temperatures, crosshead shoe (slipper) temperatures, pressure packing case temperatures, and a variety of other machinery or process temperature measurements.

Powerful cylinder pressure measurements now available for the most complete picture of reciprocating compressor health. Dynamic P-V curves, rod reversal measurements, and much more.

Single-cable Ethernet connectivity to our System 1 software for advanced diagnostics and condition monitoring functionality.

Capabilities for assessing piston rod vibration and position at precisely defined crank angles for repeatable, useful information on rider band wear, rod bow/flex, and other conditions. Also applicable to hypercompressors using plungers instead of conventional pistons.

At the heart of our Recip Monitoring Solution is the Bently Nevada* 3500 Series Machinery Protection System...
The single most important measurement for condition monitoring of reciprocating compressors is cylinder pressure. Armed with accurate cylinder pressure at each point in the piston’s stroke, a Pressure-Volume (PV) curve can be constructed that provides indispensable information on your machine’s health.

That’s why we’ve given particular attention to this vital measurement. With a robust sensor, advanced signal processing functionality in our 3500/77M Recip Cylinder Pressure Monitor, and a suite of graphical plots in System 1 software specifically for analyzing cylinder conditions, there’s simply no better way to get inside your cylinders—where the action is.

Historically, measuring these conditions meant temporarily attaching transducers to indicator valves on each cylinder. Although cumbersome, this practice was necessary because pressure transducers simply couldn’t survive under long-term exposure to the harsh environment of cylinder chambers. We knew that the key to reliable and effective assessment of machinery health—not to mention convenience—was to design a sensor that could endure 24/7 exposure to such an environment, eliminating the burden of constantly connecting and disconnecting every time you wanted data.

With our proven Bently Nevada 165855 Cylinder Pressure Transducer, we’ve done just that. It provides continuous static and dynamic pressure data and is specifically designed for use with our 3500/77M Recip Cylinder Pressure Monitor. Innovative materials and construction techniques allow it to deliver reliable measurements in the extreme temperatures, pressure cycling, and harsh chemical environments (such as H2S) inherent in reciprocating compressor cylinder applications.

Available in a variety of pressure ranges from 100 psia to 10,000 psia (68947 kPa / 689 bar), the 165855 has undergone extensive testing. In fact, we’re so confident of its performance that we offer something unique to the industry: a three-year warranty.

† U.S. Patent 6,955,090
**Pressure Versus Displaced Volume**
Plotting indicated and ideal cylinder pressure versus displaced volume enables detection of malfunctioning seals (rings, valves and unloaders). Use of log-log scales permits earlier detection of leaks. For cylinders with stepless unloaders a patented algorithm detects the valve closure point and adjusts the theoretical curves.

**Y Versus Crank Angle**
Leveraging the 3500 architecture, which simultaneously captures data across multiple channels, this plot format enables users to correlate events across different measurements and to correlate events with piston position inside the cylinder. For example, the large filtered acceleration impulse event at the cursor near 240 degrees along with the impulse event near 40 degrees probably suggests a loose piston condition exists.

**Performance Variables at a Glance**
Right click on a pressure curve to bring up this handy software variable reference box that displays the performance variables for each chamber in the cylinder. Changes in these performance variables, such as cylinder flow balance, can confirm diagnosis of valve, piston ring or pressure packing failures. These values can be collected and trended to identify long-term degradation.

**Rod Position Plots**
Rod position plots display the total movement of the plunger or piston rod at the pressure packing case. Typically, effects of changes in mechanical clearances, such as plunger to guide bearing, crosshead to crosshead guide, etc., and changes in average position, such as the thermal growth of a piston rod at cold conditions and operating conditions can be seen in this format. In this example the unloaded condition (red curve) is being compared with the loaded condition (blue curve) of the cylinder.

**Rod Load Plots**
Plotting gas and combined rod load (shown in the top left pane) with other measurements such as crosshead acceleration and rod position provides the ability to detect problems such as mechanical looseness, excessive loading and inadequate reversal. Additionally, the impulse acceleration (upper right plot) has segment bands that are user configurable for start and duration and these can be programmed for alarm conditions which can be seen in the plot. For example, the cursor at the impulse event in the acceleration waveforms correlates to a looseness in the running gear, probably resulting from a loose piston/crosshead connection nut.

**Crank Angle Overlay**
Leveraging the 3500 architecture, which simultaneously captures data across multiple channels, this plot format enables users to correlate events across different measurements within a single plot pane. The plot format incorporates graphics optimization algorithms to enhance data presentation quality. This helps the user to more quickly and accurately correlate events across multiple measurements.
Don't just protect your recips, proactively manage them with the enhanced condition monitoring and Decision Support capabilities of System 1, our most advanced software ever.

System 1 is a platform for managing every asset in your plant. It brings together a variety of condition monitoring technologies, maintenance management applications, reliability tools, process control and historian data specifically for addressing the unique needs of reciprocating compressors.

The result is a total reciprocating compressor solution, capable of providing:

- Discharge pressure
- Suction pressure
- Minimum/maximum pressure for each crankshaft revolution
- Compression ratio
- Peak rod load for both compression and tension
- Number of degrees of rod reversal
- Suction volumetric efficiency
- Discharge volumetric efficiency
- Indicated horsepower
- Capacity at suction conditions
- Capacity at discharge conditions
- Suction power losses
- Discharge power losses
- Indicated clearance volume
- Flow balance of suction to discharge
- Adiabatic median capacity between suction and discharge capacity
- Adiabatic flow balance between theoretical suction and discharge flow
- Power to median capacity ratio
- Displaced volume
- Piston animation view
- Vertical force plot
- Automated plot sessions creation

**System 1 Optimization and Diagnostic Software**

**Crank Angle Waterfall Plots**

A crank angle waterfall plot allows the user to see how events in one cycle of compression compares with other cycles over a long period of time. As such, the pressure, crosshead or cylinder acceleration, and piston rod vibration waveforms can be configured for such a plot. This enables the user to observe operational changes to the events in the waveforms. The plot on the left shows a filtered crosshead Accl signal (3–2000 Hz) and reveals that a possible mechanical looseness event occurred with a particular load step for two samples, while the overall crosshead signal on the right (3–20000 Hz) reveals the overall impact energy of the time interval. Another plot of the pressure waveform could reveal the closing point of a stepless unloader changing rapidly over a short time period—providing indication of poor process control or incomplete control loop tuning.

**Decision Support* Software: A Powerful Difference**

In addition to System 1 software’s powerful plotting, trending, and manual data analysis capabilities, you’ll find something unique: Decision Support is the component of the System 1 software platform that enables an automatic audit of its collected data against user-embedded rules and knowledge, detect mechanical or thermodynamic problems, and generate informative advisories that we call Actionable Information*.

Actionable Information advisories are configured by you, to reflect your specific operating practices and procedures. When a specific malfunction or condition is detected, System 1 software informs plant personnel what the problem is, how severe it is, and what to do about it— in real time. Cell phone, pager, PDA, e-mail, desktop and process control system pop-up windows—even conventional annunciator panels—they are all supported as ways to communicate Actionable Information advisories to the right people at the right time.

You can employ powerful built-in rules with our Recip RulePaks, ready-to-run collections of intelligent rules just for recips, and/or you can build your own rules with our extraordinarily easy-to-use RuleDesk features—just drag and drop logical and mathematical operators into any sequence of conditions that correspond to a particular malfunction. The choice is yours through a totally flexible system that lets you design rules specific to your process and machinery, automate the data analysis function, and communicate required actions and urgencies instantly to the right people—whether across the hall or across the globe.
Retrofits

We make retrofits of our instrumentation systems simple by managing the entire project. We handle everything, from drilling and tapping holes in the machine to accommodate our transducers, to packaging and configuring our monitoring systems into enclosures suitable for your plant’s environment, to pulling field wiring, to integrating our software into your plant’s IT infrastructure, to documenting every detail.

Training

Understanding the vibration and performance behavior of your machinery is the key for asset optimization. To achieve this we offer tailored training.

• Instrumentation and monitoring systems operation and maintenance: training for instrumentation Engineers, providing basic knowledge on Bently Nevada™ 3500 system and components, operation and troubleshooting procedures.

• System 1® for reciprocating compressor ‘Getting Started’ course: hands-on training on system usage, data management and interpretation to enable trainees to analyze malfunctions and use of supporting data for root cause analysis.

• Reciprocating compressor Monitoring and Diagnostic: in this course attendees learn reciprocating compressor components, mechanics, performance theory, and recip-specific diagnostic techniques. The course illustrates several failure patterns through hands-on workshops at our RecipKit and actual case histories. Completion of this course enables system users to understand the compression process and interpret vibration readings of reciprocating compressors.
Machinery Diagnostics

The mechanical and thermodynamic behavior of your reciprocating compressors is analyzed by our Machinery Diagnostics Experts; malfunctions on valves, piston rings, rider bands are analyzed as well as vibration on running gear components. Machinery Diagnostic Services (MDS) can be provided either remotely or on site, on call, periodically, or continuously. This includes:

- Start-up, commissioning and operational assistance. Data analysis, system optimization (hardware and software), fine tuning of settings and customization of data visualization and management (based on actual operations and users’ needs).

- Alarm and Event Management (daily, weekly, 24/7): The “real time” disposition of alarms to indicate machine problems, process problems or instrumentation problems.

- Baseline Audits (on site/remote), asset “baseline” and report for diagnostic and alarming purposes, so that data is available for ongoing diagnostics, minimizing nuisance alarms or missed warnings.

- Periodic Audits (on site/remote), asset audit and diagnostic report. Assessing and reporting machine condition, providing recommended actions and, where applicable, performing root cause analysis.

Risk Assessment

We can audit selected assets, or your entire plant, and provide benchmarking data on which assets present the highest business interruption and other risks, which technologies and methodologies to use to mitigate risk, and the expected ROI of investments in our solutions.

Balancing & Alignment

We balance and align virtually every type of rotating machinery found in industrial plants.

Program Management

For customers that prefer to outsource all or part of their asset management activities, we can assist. Whether your needs are focused on a specific category of assets (such as reciprocating compressors), a specific condition monitoring technology (such as lubricant analysis), or a broader scope encompassing maintenance management, reliability, condition monitoring, and other asset management functions—we have the people, and experience, to deliver the results you’re seeking.
